# Python - Dictionary

Each key is separated from its value by a colon (:), the items are separated by commas, and the whole thing is enclosed in curly braces. An empty dictionary without any items is written with just two curly braces, like this: {}.

Keys are unique within a dictionary while values may not be. The values of a dictionary can be of any type, but the keys must be of an immutable data type such as strings, numbers, or tuples.

## Accessing Values in Dictionary

To access dictionary elements, you can use the familiar square brackets along with the key to obtain its value. Following is a simple example –

```
#!/usr/bin/python

dict = {'Name': 'Zara', 'Age': 7, 'Class': 'First'}
print "dict['Name']: ", dict['Name']
print "dict['Age']: ", dict['Age']
```

When the above code is executed, it produces the following result -

```
dict['Name']: Zara
dict['Age']: 7
```

If we attempt to access a data item with a key, which is not part of the dictionary, we get an error as follows –

```
#!/usr/bin/python

dict = {'Name': 'Zara', 'Age': 7, 'Class': 'First'}
print "dict['Alice']: ", dict['Alice']
```

When the above code is executed, it produces the following result –

```
dict['Alice']:
Traceback (most recent call last):
  File "test.py", line 4, in <module>
     print "dict['Alice']: ", dict['Alice'];
KeyError: 'Alice'
```

## **Updating Dictionary**

You can update a dictionary by adding a new entry or a key-value pair, modifying an existing entry, or deleting an existing entry as shown below in the simple example –

```
#!/usr/bin/python

dict = {'Name': 'Zara', 'Age': 7, 'Class': 'First'}

dict['Age'] = 8; # update existing entry

dict['School'] = "DPS School"; # Add new entry

print "dict['Age']: ", dict['Age']

print "dict['School']: ", dict['School']
```

When the above code is executed, it produces the following result -

dict['Age']: 8 dict['School']: DPS School

#### **Delete Dictionary Elements**

You can either remove individual dictionary elements or clear the entire contents of a dictionary. You can also delete entire dictionary in a single operation.

To explicitly remove an entire dictionary, just use the **del** statement. Following is a simple example –

```
#!/usr/bin/python

dict = {'Name': 'Zara', 'Age': 7, 'Class': 'First'}
del dict['Name']; # remove entry with key 'Name'
dict.clear(); # remove all entries in dict
del dict; # delete entire dictionary

print "dict['Age']: ", dict['Age']
print "dict['School']: ", dict['School']
```

This produces the following result. Note that an exception is raised because after **del dict** dictionary does not exist any more –

```
dict['Age']:
Traceback (most recent call last):
  File "test.py", line 8, in <module>
     print "dict['Age']: ", dict['Age'];
TypeError: 'type' object is unsubscriptable
Note - del() method is discussed in subsequent section.
```

## Properties of Dictionary Keys

Dictionary values have no restrictions. They can be any arbitrary Python object, either standard objects or user-defined objects. However, same is not true for the keys.

There are two important points to remember about dictionary keys -

**(a)** More than one entry per key not allowed. Which means no duplicate key is allowed. When duplicate keys encountered during assignment, the last assignment wins. For example –

```
#!/usr/bin/python

dict = {'Name': 'Zara', 'Age': 7, 'Name': 'Manni'}
print "dict['Name']: ", dict['Name']
```

When the above code is executed, it produces the following result -

dict['Name']: Manni

**(b)** Keys must be immutable. Which means you can use strings, numbers or tuples as dictionary keys but something like ['key'] is not allowed. Following is a simple example –

```
#!/usr/bin/python

dict = {['Name']: 'Zara', 'Age': 7}
print "dict['Name']: ", dict['Name']
```

When the above code is executed, it produces the following result -

```
Traceback (most recent call last):
File "test.py", line 3, in <module>
dict = {['Name']: 'Zara', 'Age': 7};
TypeError: unhashable type: 'list'
```

## **Built-in Dictionary Functions & Methods**

Python includes the following dictionary functions -

Sr.No.	Function with Description
1	cmp(dict1, dict2)
	Compares elements of both dict.
2	len(dict)
	Gives the total length of the dictionary. This would be equal to the number of items in the dictionary.
3	str(dict)

	Produces a printable string representation of a dictionary
4	type(variable)  Returns the type of the passed variable. If passed variable is dictionary, then it would return a dictionary type.

Python includes following dictionary methods -

T yaron molades following distionary methods		
Sr.No.	Methods with Description	
1	dict.clear()	
	Removes all elements of dictionary dict	
2	dict.copy()	
	Returns a shallow copy of dictionary dict	
3	dict.fromkeys()	
	Create a new dictionary with keys from seq and values set to value.	
4	dict.get(key, default=None)	
	For key key, returns value or default if key not in dictionary	
5	dict.has_key(key)	
	Returns <i>true</i> if key in dictionary <i>dict</i> , <i>false</i> otherwise	
6	dict.items()	
	Returns a list of dict's (key, value) tuple pairs	
7	dict.keys()	
	Returns list of dictionary dict's keys	
8	dict.setdefault(key, default=None)	
	Similar to get(), but will set dict[key]=default if key is not already in dict	

9	dict.update(dict2) Adds dictionary dict2's key-values pairs to dict
10	dict.values() Returns list of dictionary dict's values
